**This report may be quoted as:** Bougher, N.L., Hart, R., Jayasekera, A., & Glossop, B. (2009). Fungi of John Forrest National Park. Perth Urban Bushland Fungi Project Report.

---

This report presents data from the Perth Urban Bushland Fungi (PUBF) Project workshop held on 12 July 2009 in John Forrest National Park - a National Park in the Perth hills region of southwest Western Australia. Participants collected fungi with Group Leaders in the eastern area of John Forrest National Park in the morning and spent the afternoon inside at the "Hub of the Hills" Community Centre in Mundaring, learning about fungi in general, their features and their roles in helping to keep bushlands healthy. They also learnt more about the fungi they had collected that morning. The event was organised with "Bush Skills for the Hills" as part of their Winter Program.

Fifty people took part in the workshop. They were divided into five groups for the morning foray, led by Mark Brundrett and Aruni Jayasekera; Roz Hart and Laurton McGurk; Joe Froudust and Margaret Langley; Kevn Griffiths and Derek Mead Hunter; and Kirsten Tullis and Louise Little; all volunteer Leaders from the PUBF Project. The fungi collected were sorted and examined and some were vouchered for permanent lodgement at the Western Australian Herbarium. Mycologist Neale Bougher identified the fungi and led the workshop.

## **John Forrest National Park**

The John Forrest National Park is situated about 25 km east of Perth's CBD on the western edge of the Darling Plateau in the Shire of Swan and Shire of Mundaring. It includes an extensive area (2,676 hectares) of lateritic soils with numerous granitic and doleritic outcrops and associated sands supporting five vegetation complexes (Department of Conservation and Land Management, 1994). Forest and woodland occur over much of the area with dominant trees such as jarrah (*Eucalyptus marginata*), marri (*Corymbia calophylla*) and wandoo (*Eucalyptus wandoo*). John Forrest National Park has a rich diversity of fungi, but prior to the current survey, few had been recorded and there were less than 10 collections from the Park vouchered and held at the Western Australian Herbarium.

## **John Forrest National Park Bushland Fungi**

During the survey at John Forrest National Park in July 2009 a total of 84 fungi were recorded, which comprised 49 different fungi species. Twelve collections were lodged with the Department of Environment and Conservation Western Australian Herbarium (Tables 1, 2).

The majority of fungi observed during this survey at John Forrest National Park were decomposer fungi. These included the mushroom types of fungi such as the ubiquitous Golden Wood Fungus

(*Gymnopilus allantopus*), pictured here fruiting out of a gumnut and bracket types such as the Lilac Bracket Fungus (*Fomitopsis lilacinogilva*). In addition, many species of mycorrhizal fungi were recorded during this survey. Mycorrhizal fungi form partnerships with native plants such as eucalypts, acacias and sheoaks (allocasuarinas). The fungi assist the plants to obtain nutrients from the soil while receiving sugars in return. The mycorrhizal fungi observed at John Forrest National Park vary considerably in form. For example, mycorrhizal fungi such as *Amanita xanthocephala* and *Cortinarius australiensis* produce mushroom fruit bodies, whereas the possibly (though untested) mycorrhizal fungus *Sistotrema* produces an inconspicuous resupinate (skin fungus) type of fruit body. Only one species of mycorrhizal truffle fungi, *Cystangium* sp. was observed during the survey. This is a small, white truffle and it occurs only about 1 to 3 cm below the surface. The lack of other truffles recorded is not surprising due to the dry conditions and because the survey focussed on finding above-ground fungi fruit bodies. It is likely that a significant representation of Australia's hundreds of species of native truffles (Bougher and Lebel, 2001) occur at John Forrest National Park. For example, a collection of the genus *Auritella*, a truffle relative of the mushroom genus *Inocybe*, is vouchered at the Western Australian Herbarium from the park.

The Yellow Headed Amanita (*Amanita xanthocephala*) – a mycorrhizal partner of native plants at John Forrest National Park and elsewhere

Many examples of fungi that are restricted to particular microhabitats were recorded. For example certain fungi such as *Psilocybe coprophila* are restricted to animal dung, *Rickenella fibula* always occurs in moss beds as it has an association with the moss, and *Lichenomphalia* only occurs wherever an inconspicuous green alga is present. It forms a lichen with the alga.

Three species of fungi with large fruit bodies that occur on living or dying trees were observed during this survey. Two of these may be pathogenic but they may also persist as decomposers for long periods of time - the Ghost Fungus (*Omphalotus nidiformis*) and the Beefsteak Fungus (*Fistulina hepatica*). A third species, the Australian Honey Fungus (*Armillaria luteobubalina*), is a pathogen capable of rapidly infecting and killing trees and shrubs (see management discussion below). Large areas of John Forrest National Park are known to be infected by this fungus (Department of Conservation and Land Management, 1994).

The Australian  
Honey  
Fungus  
*Armillaria*  
*luteobubalina*

Some of the fungi recorded in this survey remain unidentified pending further collections or more detailed comparative analyses. Many of the fungi could only be identified to genus level. This is because detailed taxonomic examinations are yet to be completed and perhaps some are undescribed species. Far more fungi are likely to occur at John Forrest National Park than the 49 species recorded in this inaugural survey. Fewer fungi than may have been expected were found in the 2009 survey due to very dry weather conditions in the weeks preceding the survey. Because of the unpredictable nature of fungi fruiting, surveys need to be conducted over many years in order to capture the biodiversity of fungi present in any given area.

## **Management recommendations for understanding and conserving fungi biodiversity at the John Forrest National Park**

Is the ecology and biodiversity of John Forrest National Park in balance for long-term health? To help answer that question, management strategies for the biodiversity of the bushland need to consider the Flora, Fauna and Fungi together. The Fungi have crucial ecological roles for maintaining bushland health, including linkages between the 3 F's. Conservation of biodiversity and general interest in the John Forrest National Park has primarily focussed on flora and fauna. An increased level of knowledge about the fungi at John Forrest National Park is required as a basis for documenting and understanding the fungi, and in turn for helping to manage and conserve the bushland's flora and fauna.

Management recommendations involving fungi include:

1. **Undertake biological surveys to build up an inventory of fungi:** John Forrest National Park has a wide range of vegetation types (Department of Conservation and Land Management 1994) that undoubtedly influence the presence, abundance and spatial distribution of fungi species in the bushland. Different fungal communities are likely to occur in different parts of the bushland. Vegetation-fungi patterns could be clarified if surveys of fungi were carried out annually over many years. Far more fungi species are likely to occur in John Forrest National Park than the species recorded so far. Due to the unpredictable nature of fungi fruiting, surveys need to be conducted several times a year over many years in order to capture the biodiversity of fungi present in any given area. Such inventory data may be used to classify fungi communities at John Forrest National Park, compare the fungi communities at the bushland with those at other bushlands, and as a baseline for monitoring changes in biodiversity at the bushland - e.g. any trends indicating changes in the diversity of significant ecological groups of fungi such as mycorrhizal species, and the effects of major disturbances such as fire or disease incursions.
2. **Record comprehensive data on surveys:** (i) the identity of the fungi (ii) the main features of the fungi (including close-up photographs) (iii) habitat (in litter, on dead wood etc.) and (iv) plant species associated with each of the fungi. Standard recording sheets for fungi biodiversity surveys are available on request from PUBF (DEC Western Australian Herbarium) or from the PUBF website at [www.fungiperth.org.au](http://www.fungiperth.org.au).
3. **Georeference the surveys:** It would be desirable to georeference future surveys at John Forrest National Park in order to build up a spatial map of distribution of individual fungi species. Such data can be overlain onto vegetation, soil and fire-age maps so as to potentially recognise associations between particular fungi and plants, or vegetation and landscape types. A georeferencing survey kit developed by John Weaver for PUBF is available on loan from the Western Australian Herbarium.
4. **Involve community:** It is recommended that further fungi surveys, involving members of the local community, be undertaken at John Forrest National Park. The involvement of local community members can facilitate a greater sampling effort, a general increase in awareness about fungi and their roles and linkages in bushlands, and a greater appreciation of the need to preserve bushland. Fungi surveys are well suited to annual involvement of Friends Groups and volunteers from the local community.
5. **Determine the mycorrhizal plant partners of fungi:** To understand the mycorrhizal relationships between fungi and plants at John Forrest National Park, a list of known plants at the Park should be annotated with the likely mycorrhizal status of each plant (e.g. categories such as, ectomycorrhizal, arbuscular, epacrid, orchid and not mycorrhizal). This will help understanding of how the pattern of occurrence of various species of fungi relates to the distribution of vegetation types at John Forrest National Park.
6. **Determine the animal interactions with fungi:** Determine what truffle fungi are present at John Forrest National Park and if they and other fungi are being used as a food resource by local mycophagous (fungus-eating) native mammals such as bandicoots. Such knowledge has

significant application if mammals are being encouraged or relocated into the area, or to help understand why there may have been declines in mammal populations at John Forrest National Park. Insects that use fungi as food and/or habitat are also likely to be present in the bushland.

7. **Management and monitoring of *Armillaria*:** Large areas of John Forrest National Park are known to be infected by *Armillaria* (Department of Conservation and Land Management, 1994). Direct management to contain particular *Armillaria* infestations is complex, and an analysis of the various intervention options is beyond the scope of this report. Management options for *Armillaria* that are often applied in gardens such as trenching or changes to soil pH are impracticable for natural bushlands. Quarantine options such as those applied for *Phytophthora* dieback are not as appropriate for *Armillaria*, due to the difference in how these vastly different organisms spread. In most cases, at least in the Perth Region, *Armillaria* infestations have been periodic, often flaring up and diminishing after a period of time. The underlying causes of such fluxes are not fully understood. The occurrence of high biodiversity of all types of fungi in bushlands and therefore the various contributions of those fungi to the overall health of bushlands may be one factor determining the frequency and severity of infestations of *Armillaria* (and other disease fungi). For John Forrest National Park, it is recommended that georeferenced surveys of *Armillaria* be undertaken to create a spatial map of the distribution of this fungus. This data can be overlain onto vegetation, soil and fire-age maps so as to potentially recognize associations between infestations and plants or vegetation and landscape types. It would be desirable to undertake the surveys successively over time to be able to monitor the spread, intensity and duration of *Armillaria* infections in John Forrest National Park.
8. **Include Flora, Fauna and Fungi in signage and interpretative material at the Park:** Due to its prominent position in the landscape and close proximity to Perth, John Forrest National Park is of high significance as a recreational reserve (Department of Conservation and Land Management, 1994). It has well-developed signage and facilities to enhance public engagement and education values of the Park. Flora, Fauna and Fungi could be included in signage and interpretative material at John Forrest National Park. This would help to promote public awareness and appreciation of the linkages between the 3Fs that influence the long-term health of the Park's bushland.
9. **Support a strategy to preserve representative landscapes:** Support a management plan that aims to preserve a variety of natural vegetation types and the diversity of plant species within the types. Also preserve a diversity of fire ages, including at least some long unburnt patches if possible. This strategy will help retain a variety of microhabitats for fungi – e.g. specific components of wood (logs, banksia bark, twigs etc.), litter, moss beds and specific mycorrhizal partner plants. In turn, this strategy may foster fungi biodiversity and may also help to limit disease incursions at John Forrest National Park.

## Georeferenced Tracks and Photos

Joe Froudust and Margaret Langley's group, 12 July 2009

The numbers on the coloured dots in the fungi photos correspond to the collecting number and usually do not match the photo number. It is the photo number preceding the fungus name which correlates with the site on the map above.
